Objectives

- Use data binding to decouple code-behind from UI
- 2. Use value converters to bind incompatible types

Use data binding to decouple code-behind from UI

Tasks

- 1. Map data to visuals
- 2. Create bindings in code
- 3. Create bindings in XAML
- 4. Work with binding context
- 5. Change binding modes
- 6. Implement property change notifications

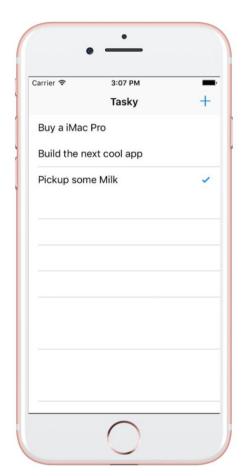

Apps are driven by data

- Most applications display and manipulate data in some form
 - internally generated
 - read from an external source

- Classes created to represent data are often referred to as Models
 - can also refer to "entity" objects

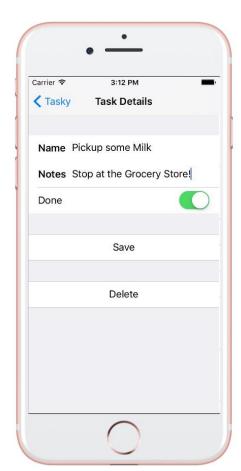

Data > Views

❖ We use code to display internal data in our pages

```
Name.Text = task.Title;
Notes.Text = task.Notes;
IsDone.IsToggled = task.Completed;
...
```

... and events to provide interactivity / behavior

```
Name.TextChanged += (sender, e) =>
     task.Title = Name.Text;
IsDone.Toggled += (sender, e) =>
     task.Completed = IsDone.IsToggled;
```

Data > Views in code

This approach works, and for small-ish applications is perfectly adequate but it has disadvantages as the application grows in complexity

Updates to data are not centralized

Relationships in data or UI behavior is harder to manage

Hard to unit test

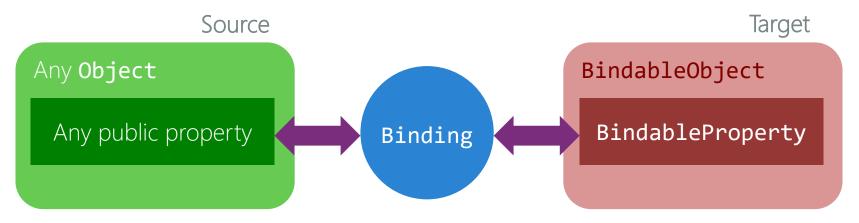

UI is tightly coupled to the code behind logic, changes ripple through code

Introducing: Data Binding

❖ Data Binding involves creating a loose relationship between a source property and a target property so that the source and target are unaware of each other

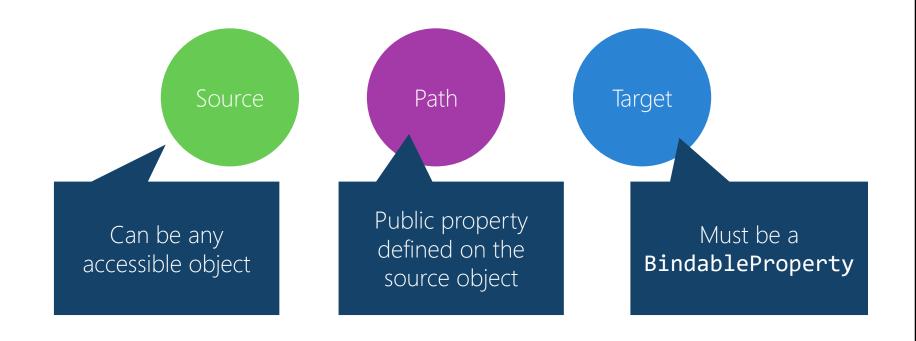

Binding acts as an *intermediary* – moving the data between the source and target

Creating Bindings in Xamarin.Forms

Bindings require three pieces of information

Task Details

Save

Delete

Creating bindings [Source]

object defined in our application

```
Todo task = new ToDo() { Title = "Pickup some Milk", ... };
Entry Name = new Entry();
                                                                              Name Pickup some Milk
                                                                              Notes Stop at the Grocery Store!
Binding nameBinding = new Binding();
nameBinding.Source = task;
          Binding identifies the source of the
         binding data – this is where the data
       comes from, in this case it's a single ToDo
```

Creating bindings [Path]

```
Todo task = new ToDo() { Title = "Pickup some Milk", ... };
Entry Name = new Entry();
Binding nameBinding = new Binding();
nameBinding.Source = task;
nameBinding.Path = "Title";
            Binding identifies the property path which
```

Task Details Name Pickup some Milk Notes Stop at the Grocery Store! Save Delete

Binding identifies the *property path* which identifies a property on the source to get the data from, in this case we want to get the value from the **Todo.Title** property

Creating bindings [Path]

```
Todo task =
                       More Path Examples
Entry Name =
                                                                      Task Details
                  new Binding("Property")
                  new Binding("Property.Child")
                                                                  Name Pickup some Milk
Binding nameB
                                                                  Notes Stop at the Grocery Store!
                  new Binding("Property[Key]")
nameBinding.S
                  new Binding("Property[1]")
nameBinding.P
                  new Binding("[Key]")
                  new Binding(".")
```

Creating bindings [Target]

```
Todo task = new ToDo() { Title = "Pickup some Milk", ... };
Entry Name = new Entry();
Binding nameBinding = new Binding();
nameBinding.Source = task;
nameBinding.Path = "Title";
Name.SetBinding(Entry.TextProperty, nameBinding);
```

Task Details Name Pickup some Milk Notes Stop at the Grocery Store! Delete

Binding is associated to the target property using the BindableObject.SetBinding method

Creating bindings [Target]

```
Todo task = new ToDo() { Title = "Pickup some Milk", ... };
Entry Name = new Entry();
Binding nameBinding = new Binding();
nameBinding.Source = task;
nameBinding.Path = "Title";
Name.SetBinding(Entry.TextProperty, nameBinding);
```

Task Details Name Pickup some Milk Notes Stop at the Grocery Store! Delete

This is passed the specific target property the binding will work with – this must be a **BindableProperty**

Task Details

Delete

Name Pickup some Milk

Notes Stop at the Grocery Store!

Creating bindings [Target]

```
Todo task = new ToDo() { Title = "Pickup some Milk", ... };
Entry Name = new Entry();
Binding nameBinding = new Binding();
nameBinding.Source = task;
nameBinding.Path = "Title";
Name.SetBinding(Entry.TextProperty, nameBinding);
```

... and the binding which identifies the source and the property on the source to apply

Creating bindings [XAML]

Create bindings in XAML with {Binding} markup extension

```
<StackLayout Padding="20" Spacing="20">
   <StackLayout.Resources>
      <ResourceDictionary>
         <Todo x:Key="getMilk" Title="Pickup some Milk" />
      </ResourceDictionary>
                                                                {Binding} takes the
   </StackLayout.Resources>
                                                                Path as the first
   <Entry Text="{Binding Title, ←</pre>
                 Source={StaticResource getMilk}}" />
                                                                unnamed argument
</StackLayout>
                                                                Source supplied
         Assigned to Target property
                                                                through resource
```

Data binding source

- Pages often display properties from a small number of data objects
- Can set the binding source on each binding separately, or use the BindingContext as the default binding source

```
public class Todo
      public string Title { get; set; }---
      public string Notes { get; set; }
public bool Completed { get; set;
Name Pickup some Milk <-----
Notes Stop at the Grocery Store! <-----
Done
```

Multiple Bindings

❖ BindingContext supplies the source for any binding associated with a view when the Binding.Source property is not set

Useful to use a generic form of **SetBinding** to create bindings with typed properties when establishing bindings in code, notice we are *not* setting a source property on the binding – instead, it will use **BindingContext**

BindingContext inheritance

❖ BindingContext is automatically *inherited* from parent to child – can set it once on the root view and it will be used for all children

```
public partial class TaskyDetailsPage : ContentPage
{
    public TaskyDetailsPage (Todo task)
    {
        BindingContext = task;
        InitializeComponent ();
    }
}

Save
```

BindingContext inheritance

❖ BindingContext is automatically *inherited* from parent to child – can set it once on the root view and it will be used for all children

```
BindingContext = new Todo() { Title = "Buy a Surface Studio" };
```

```
<StackLayout Padding="20" Spacing="20">
     <Entry Text="{Binding Title}" />
     <Entry Text="{Binding Notes}" />
     <Switch IsToggled="{Binding Completed}" />
     </StackLayout>
```

By setting the binding context to the **Todo**, no explicit source is necessary in XAML

Group Exercise

Using Data Binding in a Xamarin. Forms Application

View-to-View Bindings

❖ {x:Reference} identifies named elements in the same XAML page – can use this to provide a source to a Binding

Creating two-way bindings

- ❖ Typically want data to be bi-directional
 - source > target (always happens)
 - target > source (optional)

```
Notes.TextChanged += (sender, e)
=> task.Notes = Notes.Text;
```

Binding Mode

Binding Mode controls the direction of the data transfer, can set to "TwoWay" to enable bi-directional bindings

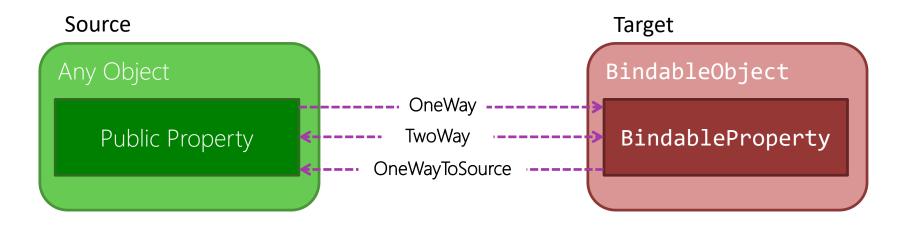

```
Source Property must
have public setter

Notes.SetBinding(Entry.TextProperty,
    new Binding("Notes") {
    Mode = BindingMode.TwoWay
});

Manually controlled through the
    Binding.Mode property
```

Available Binding Modes

BindingMode.Default is the default value and it decides the mode based on the target property preference – either **OneWay** or **TwoWay**

Default Binding Mode

❖ Default binding mode is *property-specific*, most are <u>one-way</u> by default with a few exceptions that default to two-way

DatePicker.Date SearchBar.Text

Entry.Text Stepper.Value

ListView.SelectedItem Switch.IsToggled

MultiPage<T>.SelectedItem TimePicker.Time

Picker.SelectedIndex

XAML platforms handle **binding modes differently**, best practice to get in the habit of explicitly setting the mode if it's not one-way – even if it defaults to what you want

Pushing changes to the UI

One-Way and Two-Way bindings always update the UI when the <u>source</u> <u>property</u> is changed

```
task.Notes = "Buy Groceries";

public class Todo
{
  public string Title { get; set; }
  public string Notes { get; set; }
  public DateTime By { get; set; }
  public bool Completed { get; set; }
}
O:
How could
Xamarin.Forms know
Notes has changed?
```

INotifyPropertyChanged

❖ INotifyPropertyChanged provides change notification contract, should be implemented by any modifiable model object you bind to

```
namespace System.ComponentModel
{
   public interface INotifyPropertyChanged
   {
     event PropertyChangedEventHandler PropertyChanged;
   }
}
```

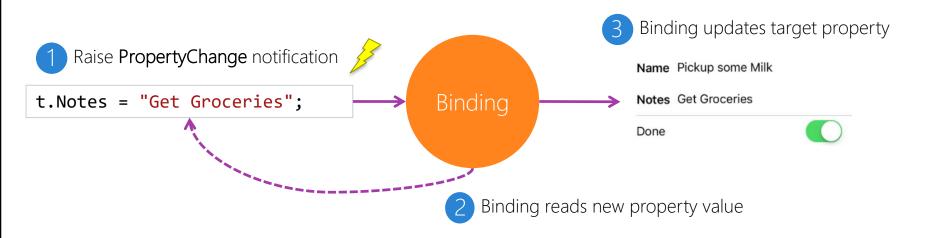

Implementing INotifyPropertyChanged

```
public class Todo : INotifyPropertyChanged
    public event PropertyChangedEventHandler PropertyChanged;
    string notes;
                                                  Must raise the PropertyChanged
    public string Notes {
        get { return notes; }
                                                event when any property is changed
        set {
                                                  - otherwise the UI will not update
            if (notes != value) {
                 notes = value;
                PropertyChanged?.Invoke(
                  this, new PropertyChangedEventArgs(nameof(Notes));
```

INPC + Bindings

❖ Binding will subscribe to the **PropertyChanged** event and update the target property when it sees the source property notification

Individual Exercise

Keeping the UI and data in sync using Bindings

- ① The source data is supplied through _____ (Select all that apply).
 - a) DataContext property
 - b) Binding. Source property
 - c) BindingContext property
 - d) None of the above

- 1 The source data is supplied through _____ (Select all that apply).
 - a) DataContext property
 - b) Binding.Source property
 - c) BindingContext property
 - d) None of the above

- 2 The source can be any object
 - a) True
 - b) False

- 2 The source can be any object
 - a) <u>True</u>
 - b) False

- 3 The target can be any object
 - a) True
 - b) False

- 3 The target can be any object
 - a) True
 - b) False

- 4 Model objects should perform the following steps when a property setter is called (pick the best answer):
 - a) Change the property and raise the PropertyChanged event
 - b) Check if the property is different, change the property and raise the PropertyChanged event
 - c) Check if the property is different, raise the PropertyChanged event and then change the property
 - d) None of these are correct

- 4 Model objects should perform the following steps when a property setter is called (pick the best answer):
 - a) Change the property and raise the PropertyChanged event
 - b) <u>Check if the property is different, change the property and raise the PropertyChanged event</u>
 - c) Check if the property is different, raise the PropertyChanged event and then change the property
 - d) None of these are correct

Summary

- 1. Map data to visuals
- 2. Create bindings in code
- 3. Create bindings in XAML
- 4. Work with binding context
- 5. Change binding modes
- 6. Implement property change notifications

Use value converters to bind incompatible types

Tasks

- 1. Perform textual conversions in XAML
- 2. Create a value converter
- 3. Apply a value converter in XAML

Simple Textual Conversions

❖ Binding can do simple, text formatting when going from Source > Target

```
public double BillAmount { get; set; }
```

Binding calls a **String.Format** passing the specified format string and the source value before assigning it to the target

You Owe: \$26.75

Going beyond textual formatting

❖ Bindings attempt to **automatically coerce data** when C# would allow it, but sometimes the data available isn't quite what the UI needs to display

Want the text color to change based on the password strength

Value Converters

- Value Converters enable type coercion and formatting
- Assigned to Converter property of Binding
- Supports optional parameter (Binding.ConverterParameter)

Convert used for source → target
ConvertBack used for target → source

conversions or even completely

different objects!

Creating a Value Converter

```
public class PWStrengthConverter : IValueConverter
   public object Convert(object value, Type targetType, object parameter, CultureInfo culture)
       PasswordStrength pwdstr = (PasswordStrength) value;
       return Color.Red;
   public object ConvertBack(object value,
                                                             Converter performs whatever
       throw new NotSupportedException();
                                                           translation is necessary to provide
                                                          target with data – this can be simple
```

Creating a Value Converter

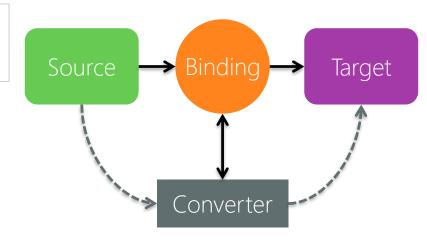

```
Provides backwards conversion for
public class PWStrengthConverter
                                     two-way binding, or can throw
                                   exception if this is not supported –
                                                                            ureInfo culture)
   public object Convert(object v
                                     this will cause a runtime failure
       PasswordStrength pwdstr =
       return Color.Red;
   public object ConvertBack(object value, Type targetType, object parameter, CultureInfo culture)
       throw new NotSupportedException();
```

Using a Value Converter

Value Converter is assigned to the binding Converter property

```
var binding = new Binding("PasswordStrength"){
   Converter = new PWStrengthConverter()
};
<ContentPage.Resources>
  <ResourceDictionary>
    <c:PWStrengthConverter x:Key="pwsCvt"/>
  </ResourceDictionary>
</ContentPage.Resources>
<Label TextColor="{Binding PasswordStrength,</pre>
    Converter={StaticResource pwsCvt}}" />
```

Binding passes values through converter

Debugging Bindings

❖ Can use dummy converter to debug data bindings – gets called during the data transfer and provides for a convenient breakpoint location

Check out https://github.com/xamarinhq/xamu-infrastructure for several great reusable value converters – including this one

Individual Exercise

Using Value Converters

- ① IValueConverter.Convert is called when going from ____ to ____
 - a) Source > Target
 - b) Target > Source

- ① IValueConverter.Convert is called when going from ____ to ____
 - a) Source > Target
 - b) Target > Source

- ② To pass a binding-specific parameter to a value converter, you can set the _____ property.
 - a. Parameter
 - b. ConversionParameter
 - c. ConverterParameter
 - d. BindingParameter

- 2 To pass a binding-specific parameter to a value converter, you can set the _____ property.
 - a. Parameter
 - b. ConversionParameter
 - c. <u>ConverterParameter</u>
 - d. BindingParameter

- 3 Binding.StringFormat can be used to convert an integer type to a double type
 - a. True
 - b. False

- 3 Binding.StringFormat can be used to convert an integer type to a double type
 - a. True
 - b. False

Summary

- 1. Perform textual conversions in XAML
- 2. Create a value converter
- 3. Apply a value converter in XAML
